Project 0

This project ran on the Flip virtual machine, which achieved peak performance of 1536.44 MegaMults/sec with one thread and 3150.42 MegaMults/sec with four threads. The data collected in the two tests resulted in a speedup of 2.05. This speedup shows that multiple threads working in parallel are much more efficient than a single thread, although it does not show linear speedup; instead, it shows a sublinear speedup as resources are stretched thin and the memory bus becomes a bottleneck. The resulting Parallel Fraction for these tests is  $F_p = 0.68$ .
